

Result-first: make the held-out finding impossible to miss

Best for a research poster session where readers decide in seconds whether to stop.

1 One-sentence takeaway + three number tiles

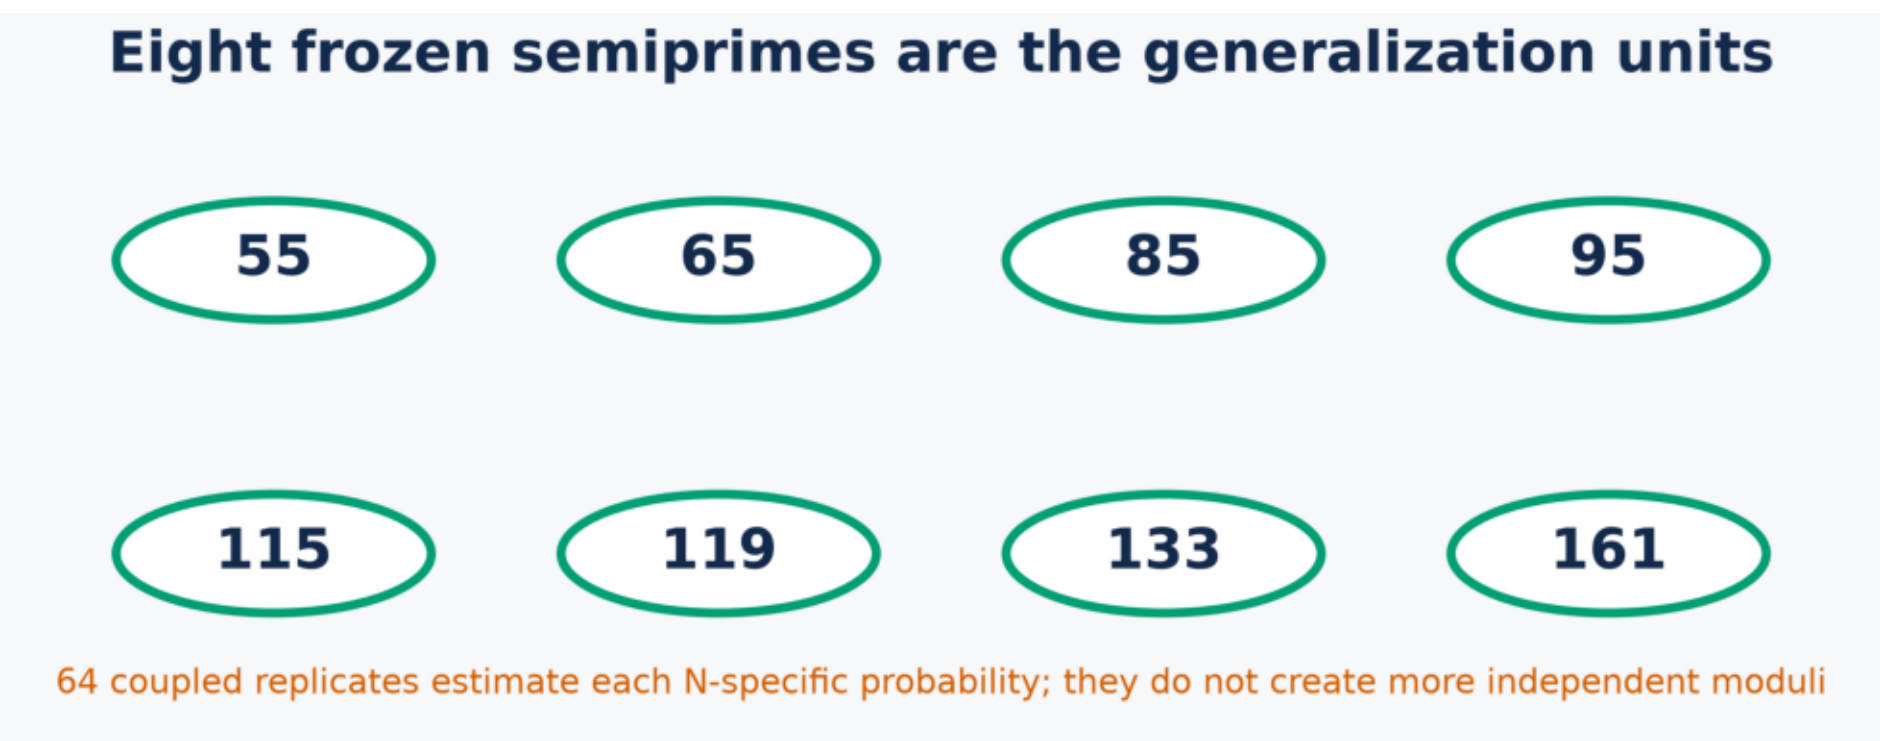

Lead with the narrow empirical result. Put the original certificate prediction beside the best held-out truncation and the QFT-only resource counts; do not state whole-algorithm speedup.

2 Research question

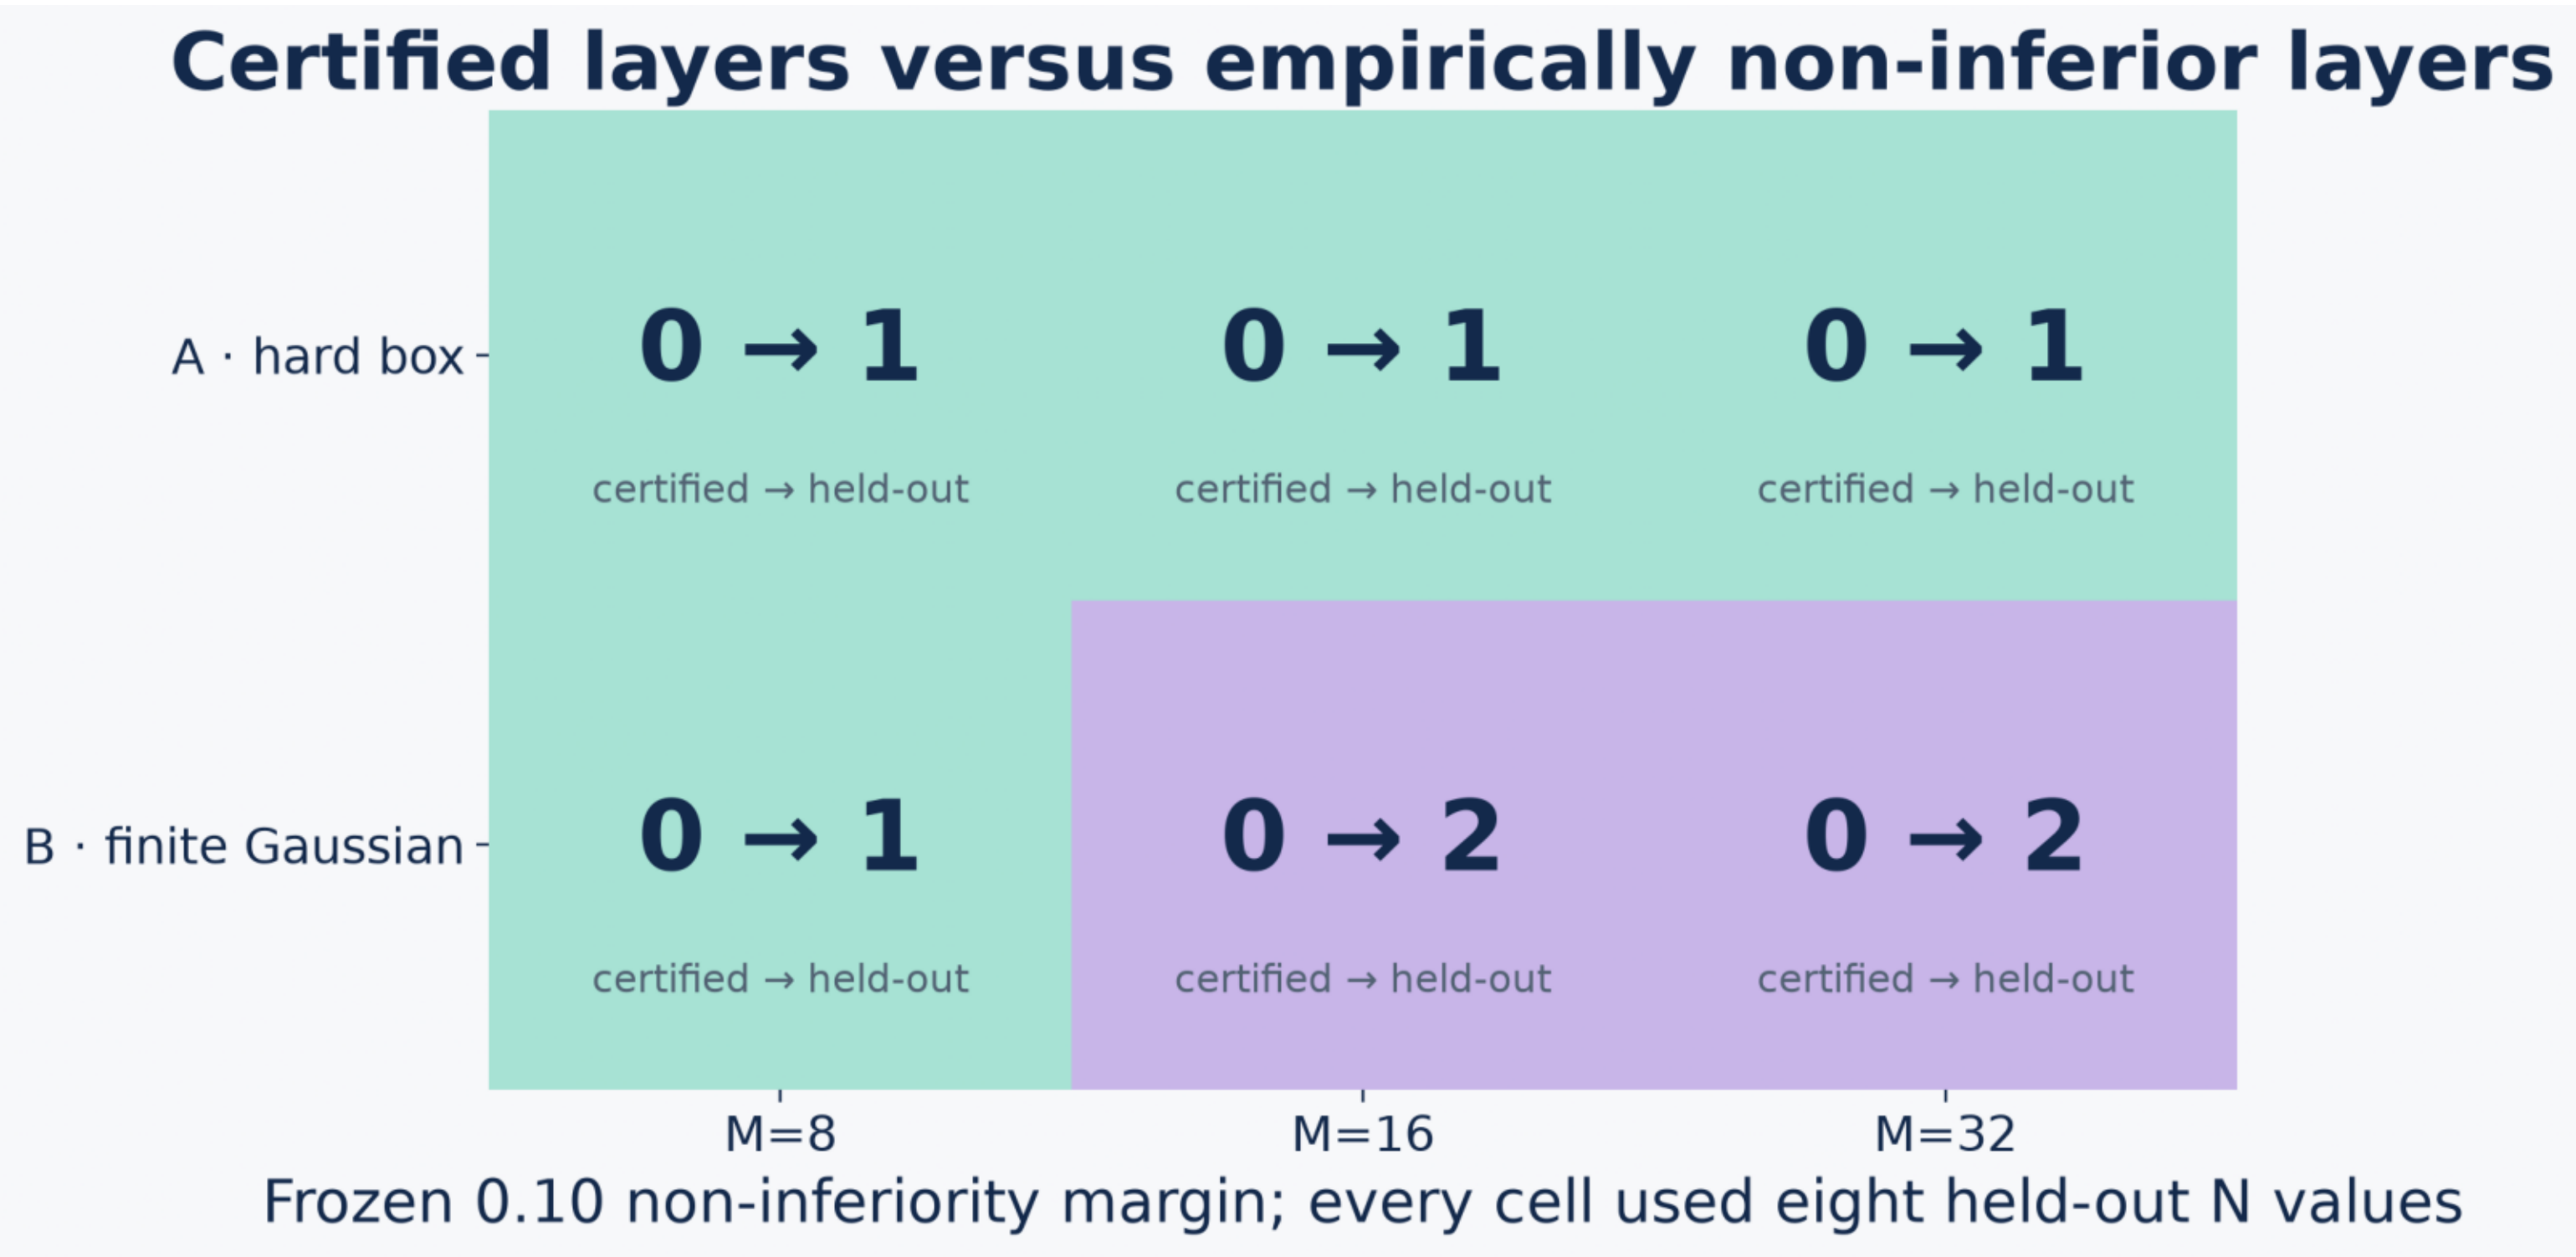

Show exactly what is being removed from the QFT.

3 Experimental design

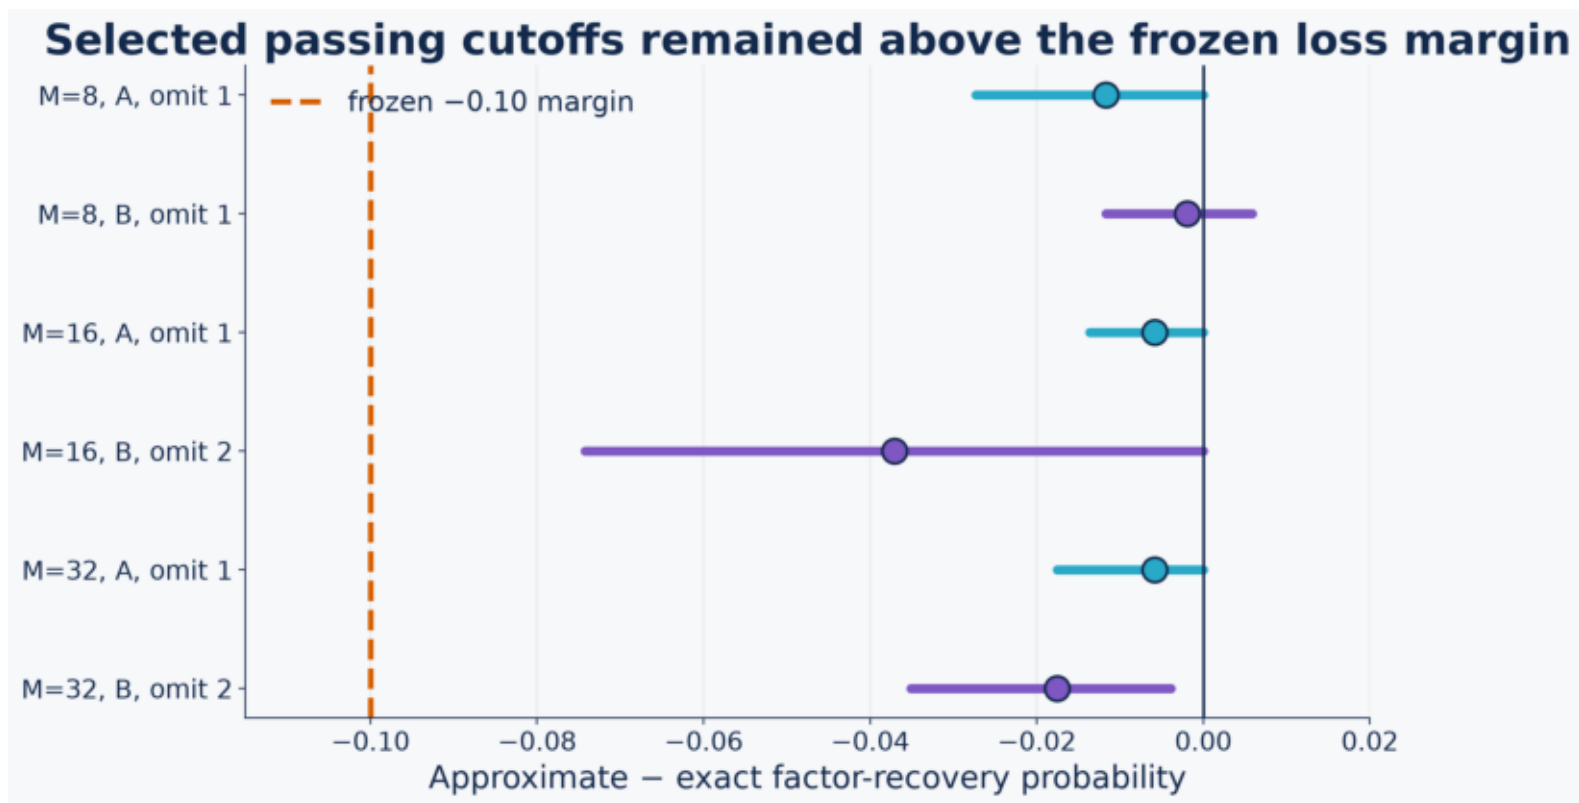

Make N—not repeated shots—the unit of generalization.

4 Hero result

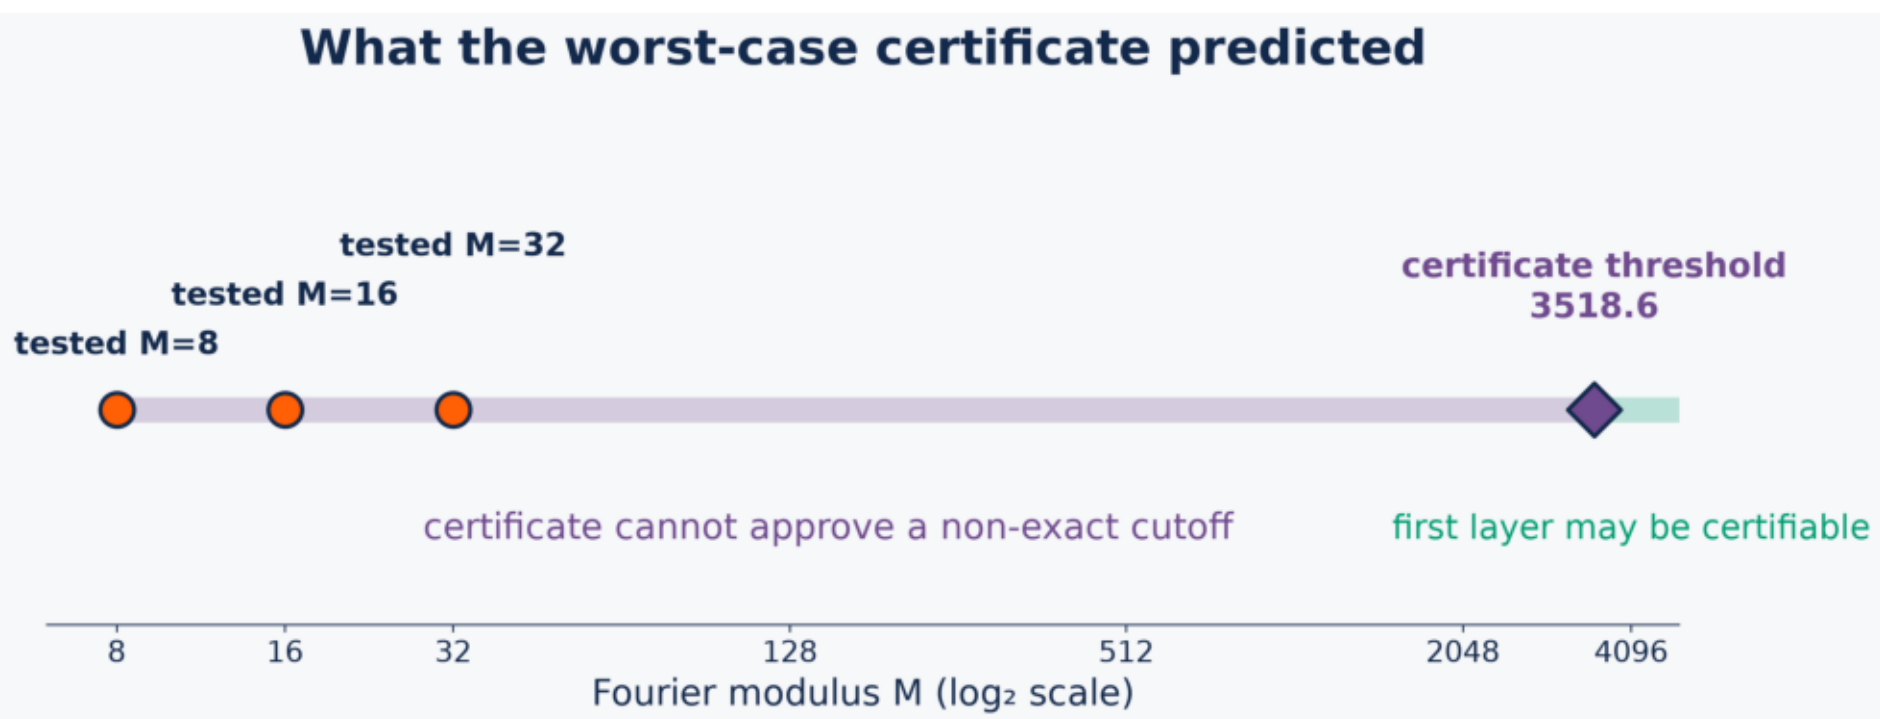

Give this plot the most area on the page.

5 Whole-N uncertainty

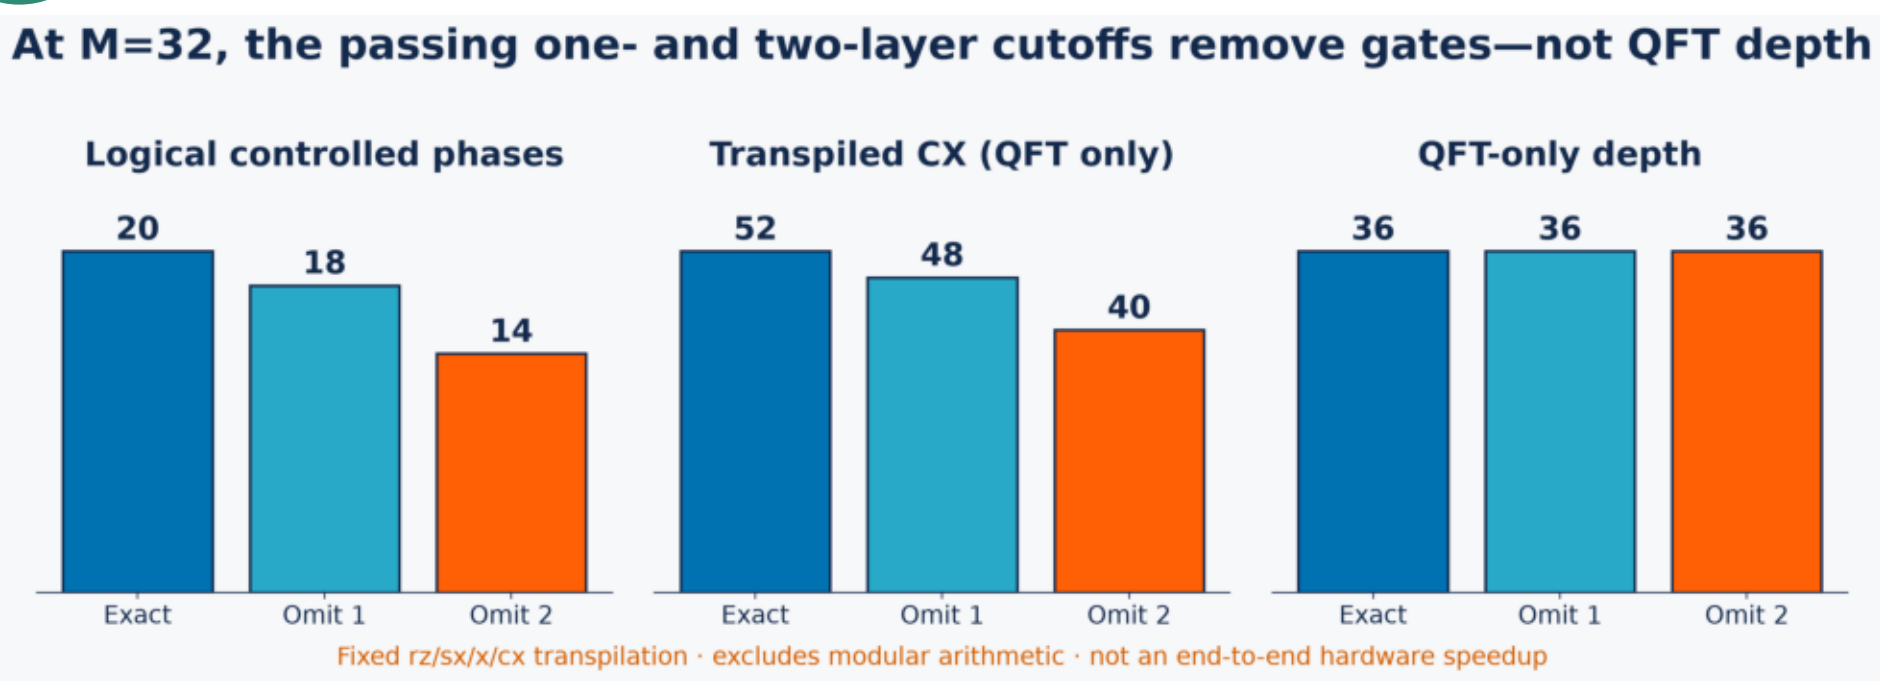

Place immediately under the hero result.

6 Certificate gap

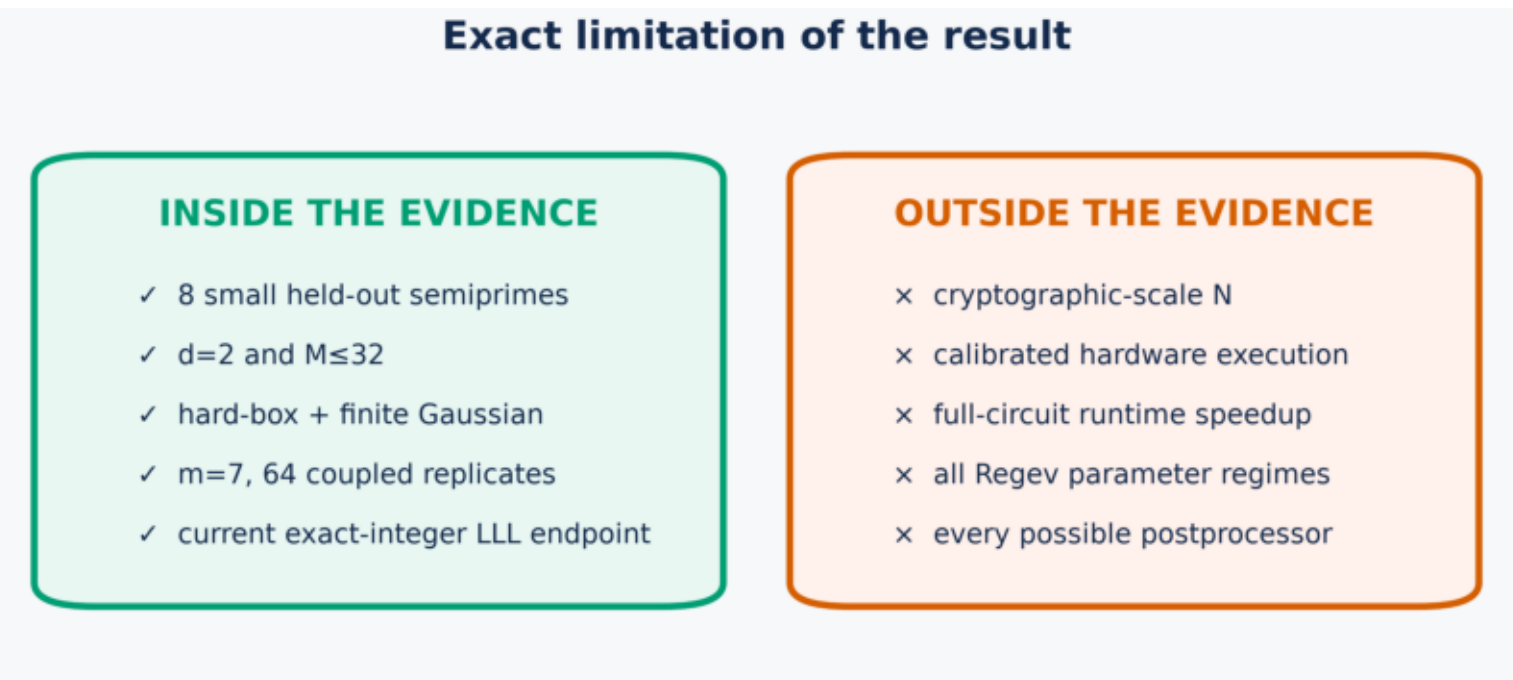

Explain the finite-regime disagreement.

7 QFT-only resources

Separate phase-gate and QFT-only CX counts.

8 Scope fence

Use explicit verified / unverified language.

9 Method in 40 words

Finite exact distributions, paired random draws, frozen parameters, and whole-modulus inference. Link to the notebook and full protocol with a QR code.

10 Limit in 40 words

Toy finite models are evidence about this implementation regime. They are not proof that approximate QFT is safe for asymptotic Regev factoring or on hardware.
